Rare decays and tests of lepton flavour universality in (b-)quark flavour physics Monica Pepe Altarelli (CERN)

On behalf of LHCb, also including material from Belle, BaBar, ATLAS and CMS

Corfu Summer Institute Workshop on the Standard Model and Beyond, September 2-10 2017

when exchanged in a loop

 Indirect approach to New Physics searches, complementary to that of ATLAS/CMS • Strategy: use well-predicted observables to look for deviations

Why rare b decays

• In the SM, processes involving flavour changes between two up-type quarks (u,c,t) or between two down-type quarks (d,s,b) are forbidden at tree level and can only occur at loop level (penguin and box) \rightarrow Rare

changing neutral currents, FCNC

• A new particle, too heavy to be produced at the LHC, can give sizeable effects

One of the milestones of flavour programme $B_{(s)} \rightarrow \mu^+ \mu^-$ Very suppressed in the SM - Loop, CKM ($|V_{ts}|^2$ for B_s) and helicity $\sim \left(\frac{m_\mu}{M_B}\right)^2$ \xrightarrow{b} $\xrightarrow{W^-}$ \xrightarrow{s} μ_+^+ • Theoretically "clean" \rightarrow precisely predicted $\mathcal{B}(B_s^0 \to \mu^+ \mu^-) = (3.65 \pm 0.23) \times 10^{-9} ~(\sim 6\%)$ $\mathcal{B}(B^0 \to \mu^+ \mu^-) = (1.06 \pm 0.09) \times 10^{-10}$ Sensitive to NP - A large class of NP theories, such as SUSY, predict significantly higher values for the $B_{(s)}$ decay probability • Very clean experimental signature - Studied by all high-energy hadron collider experiments

Straub, arXiv:1107.0266

 $\Gamma(B_s(t) \to \mu^+ \mu^-) \equiv \Gamma(B_s^0(t) \to \mu^+ \mu^-) + \Gamma(\overline{B}_s^0(t) \to \mu^+ \mu^-)$ $\propto (1 - A_{\Delta\Gamma_s})e^{-\Gamma_L t} + (1 + A_{\Delta\Gamma_s})e^{-\Gamma_H t}$

 $A_{\Delta\Gamma} \equiv \frac{\Gamma(B_s^H \to \mu^+ \mu^-) - \Gamma(B_s^L \to \mu^+ \mu^-)}{\Gamma(B_s^H \to \mu^+ \mu^-) + \Gamma(B_s^L \to \mu^+ \mu^-)}$

In SM $A_{\Delta\Gamma}$ = 1, i.e. B_s system evolves with the lifetime of the heavy $B_{\rm s}$ mass eigenstate, but in NP scenarios $A_{\Delta\Gamma}$ could be anywhere in range [-1,1]

• A new observable sensitive to NP and complementary to branching fraction • For $B_{\rm s}$ mesons, the sizeable difference between the decay widths of the light and heavy mass eigenstates $\Delta\Gamma_s$ allows us to define:

15

$$\tau_{\rm eff} = \frac{\tau_{B_{\rm s}}}{1 - y_{\rm s}^2} \frac{1 + 2}{1}$$

• First measurement by LHCb, not yet

Results on teff

measurements by fitting a single exponential function

 $2A_{\Delta\Gamma}y_{\rm s} + y_{\rm s}^2$ where $+ A_{\Delta\Gamma} y_{\rm s}$

 $\tau_{\rm eff}(B_{\rm s}(t) \to \mu^+ \mu^-) = (2.04 \pm 0.44 \pm 0.05) \, ps$

sensitive to $A_{\Delta\Gamma}$, but interesting as a proof-of-principle measurement, which can be scaled to higher luminosities

LHCb measured effective lifetime from the decay time distributions of the samples of untagged $B_{\rm s}$ events used for the branching fraction

$$y_{\rm s} = \tau_{B_{\rm s}} \frac{\Delta \Gamma}{2}$$

PRL 118 (2017) 191801

- In the SM, larger BF due to larger τ mass $(m_{\tau}^2/M_{\rm B}^2)$ $\mathcal{B}(B_{s}^{0} \to \tau^{+} \tau^{-}) = (7.73 \pm 0.49) \times 10^{-7}$ $\mathcal{B}(B^0 \to \tau^+ \tau^-) = (2.22 \pm 0.19) \times 10^{-8}$
- But experimentally challenging due to undetected neutrinos in final state
- Searched by LHCb through the decay $\tau^- \to \pi^- \pi^+ \pi^- \nu_{\tau}$
- $B_{s,d}$ unresolvable in mass \rightarrow analysis optimised for $B_{\rm S}$
 - then fit MVA
- Limits set:

• Exploit intermediate $\rho(770)^0$ resonance to define signal/control regions of $m_{\pi^-\pi^+}$,

PRL 118 (2017) 251802 $\mathcal{B}(B_{\rm s} \to \tau^+ \tau^-) < 6.8 \times 10^{-3}$ at 95% C.L. $\mathcal{B}(B_{\rm d} \to \tau^+ \tau^-) < 2.1 \times 10^{-3}$ at 95% C.L.

Bobeth et al. PRL 112 (2014) 101801

Another interesting rare decay: $B^0 \to K^{*0} (\to K^+ \pi^-) \mu^+ \mu^-$

- NP can be competitive with SM processes
- Four final state particles with rich phenomenology, plethora of observables, which can be built from the measured amplitudes
- Rates, angular distributions and asymmetries sensitive to NP
- A lot of phenomenological work invested in defining observables with "clean" theoretical predictions.
 - Observables form-factor free at leading order - Still susceptible to non-factorisable corrections
- Question: how clean?

• A b \rightarrow s transition that only proceeds via loop diagrams

Is the SM prediction less precise than what is claimed?

• One such observable is so-called P'₅, not intuitive, but constructed from angular observables to be robust from 'form-factor uncertainties'

LHCb: JHEP 02 (2016) 104 Belle: PRL 118 (2017) 111801 ATLAS-CONF-2017-023 CMS-PAS-BPH-15-008

Intriguing set of results in differential branching fractions for $b \rightarrow s\mu\mu$ transitions

In general, data tend to be lower than theory predictions

Tests of Lepton Flavour Universality

Lepton Flavour Universality

• The property that the three charged leptons (e, μ , τ) couple in a universal way to the SM gauge bosons

• In the SM the only flavour non-universal terms are the three lepton masses

• If NP couples in a non-universal way to the three lepton families, then we can discover it by comparing classes of rare decays involving different lepton pairs (e.g. e/μ or μ/τ)

of lepton flavour universality

• $b \to s \ell \ell$ flavour-changing neutral currents with amplitudes involving loop diagrams

• These ratios are clean probes of NP :

- Sensitive to possible new interactions that couple in a non-universal way to electrons and muons

- Small theoretical uncertainties because hadronic uncertainties cancel: in SM, $R_{\rm H} = 1$ neglecting lepton masses, with QED corrections at ~% level

• LHCb performed measurement $d\Gamma/dq^2$ in two q^2 bins that are sensitive to different NP contributions:

- Low-q² bin: [0.045,1.1] GeV²

- Central- q^2 bin: [1.1,6.0] GeV²

0

4m

25

• Lepton identification is anything but universal!

- but incomplete
 - bremsstrahlung clusters
- than for muons (~ 1.5 to 1.8 GeV).

A very challenging measurement

- Electrons emit a large amount of bremsstrahlung, degrading momentum and mass resolution

- Recovery procedure in place for bremsstrahlung

energy threshold of bremsstrahlung photons $E_T > 75$ MeV, calorimeter acceptance and resolution, presence of energy deposits wrongly interpreted as

- Due to higher occupancy of calorimeters, trigger thresholds are higher for electrons (~2.5 to 3.0 GeV)

- Mitigated by selecting decays with electrons using hadron trigger either fired either by K^* products (hadron) or by any other particle in the event not associated with signal (TIS)

A very challenging measurement

• Due to bremsstrahlung the reconstructed B mass is shifted towards lower values and events leak into the central-q² bins

JHEP 08 (2017) 055

Measure as a double ratio

• To mitigate muon and electron differences due to bremsstrahlung and trigger, measurement performed as a double ratio with "resonant" control modes $B^0 \to J/\psi K^*$ which are not expected to be affected by NP:

 $R_{\mathrm{K}^{*0}} = \frac{\mathcal{B}(B^0)}{\mathcal{B}(B^0 \to K^*)}$

→ Relevant experimental quantities: yields & efficiencies for the four decays

 Similarities between the experimental efficiencies of the non resonant and resonant modes ensure a substantial reduction of systematic uncertainties in the double ratio

Efficiencies evaluated from simulation, tuned to data using dedicated control samples

Blind analysis to avoid experimental biases

$$\frac{\rightarrow K^{*0}\mu^+\mu^-)}{K^{*0}J/\psi(\rightarrow\mu^+\mu^-))} / \overline{\mathcal{B}}$$

 $\mathcal{B}(B^0 \to K^{*0}e^+e^-)$ $\mathcal{B}(B^0 \to K^{*0}J/\psi(\to e^+e^-))$

Fit to the invariant masses

 $LOW-Q^2$

Precision of measurement driven by statistics of electron sample : ~90 and 110 signal candidates in low-q² and central-q², muon sample 3-5 times larger 29

Central- q^2

JHEP 08 (2017) 055

$B^0 \to K^* J/\psi (\to \ell^+ \ell^-)$

 $R_{K^*} = \begin{cases} 0.66^{+0.11}_{-0.07} \,(\text{stat}) \pm 0.03 \,(\text{syst}) & \text{for } 0.045 < q^2 < 1.1 \,\text{GeV}^2 & 2.1 - 2.3 \,\sigma \\ 0.69^{+0.11}_{-0.07} \,(\text{stat}) \pm 0.05 \,(\text{syst}) & \text{for } 1.1 < q^2 < 6.0 \,\text{GeV}^2 & 2.4 - 2.5 \,\sigma \end{cases}$ 30

-candidate) and track multiplicity

Crosschecks

• $r_{J/\psi} = \frac{\mathcal{B}(B^0 \to K^{*0}J/\psi(\to \mu^+\mu^-))}{\mathcal{B}(B^0 \to K^{*0}J/\psi(\to e^+e^-))} = 1.043 \pm 0.006 \pm 0.045$

very stringent test of absolute scale of efficiencies that does not benefit from the cancellation of the experimental systematics from the double ratio compatible with being independent of decay kinematics (p_{T} , η of the B^0

• $R_{\psi(2S)} = \frac{\mathcal{B}(B^0 \to K^{*0}\psi(2S)(\to \mu^+\mu^-))}{\mathcal{B}(B^0 \to K^{*0}J/\psi(\to \mu^+\mu^-))} \left/ \begin{array}{c} \mathcal{B}(B^0 \to K^{*0}\psi(2S)(\to e^+e^-)) \\ \mathcal{B}(B^0 \to K^{*0}J/\psi(\to e^+e^-)) \end{array} \right. \rightarrow \text{compatible with}$ expectation

• $\mathcal{B}(B^0 \to K^{*0} \mu^+ \mu^-)$ in agreement with JHEP 04 (2017) 142

• $\mathcal{B}(B^0 \to K^{*0}\gamma)$ compatible with expectations

• If corrections to simulation are not accounted for, the ratio of the efficiencies (and thus R_{K^*}) changes by less than 5%

JHEP 08 (2017) 055

Electron-trigger categories

• Delta log-likelihood for the three electron-trigger categories, separately and combined

Areminder: Rk

• LHCb published an analysis of R_{k} based on Run 1 data:

$R_{\rm K} = 0.745^{+0.090}_{-0.074} \,(\text{stat}) \pm 0.036 \,(\text{syst})$

LHCb: PRL 113 (2014) 151601

aBar:	PRD 86 (2012) 032012
elle:	PRL 103 (2009) 171801

What happens next?

• Work in progress in LHCb to update $R_{\rm K}$ with additional Run 2 data - from ~250 B+ \rightarrow e+e- candidates to ~800, plus analysis is being improved • Can make analogous measurement with $B_s \rightarrow \phi \ell^+ \ell^- \rightarrow R_\phi$ and other similar modes • Run 2 update of R_{K^*} • Extend the analysis to high-q² region, above $\psi(2S)$ • Available data should be sufficient to clarify the picture

Another puzzling result in tree-level $b \rightarrow c$ transitions

- precisely predicted: $R(D^*)_{\rm SM} = 0.257 \pm 0.03$

36

• Signal and normalization channel share same final state \rightarrow most systematics cancel in ratio (trigger, PID, selection...) • Separation between B and 3π vertices ($\Delta z > 4\sigma_{\Delta z}$) crucial to obtain the required rejection of $B \rightarrow D^* 3\pi X$)

Analysis strategy

37

Background reduction

Requiring a minimum distance between B and τ vertices gives factor 10³ arXiv:1708.08856 suppression while retaining ~35% of signal

Blind analysis

Events

• This measurement:

• LHCb muonic:

• Preliminary LHCb average: $R(D^*) = 0.306 \pm 0.027$

 $R(D^*) = 0.304 \pm 0.015$ ~3.4 σ

Results

$R(D^*) = 0.285 \pm 0.019_{\text{stat}} \pm 0.025_{\text{syst}} \pm 0.014_{\text{ext}}$ consistent with SM and with previous determinations

$R(D^*) = 0.336 \pm 0.027_{\text{stat}} \pm 0.030_{\text{syst}}$

New HFLAV preliminary world average

arXiv:1708.08856

$R(D) vs R(D^*)$

Prospects • LHCb: a whole programme of semi-tauonic measurements : $R(J/\psi): B_c^+ \to J/\psi \tau^+ \nu_{\tau}$ $R(D^-): B^0 \to D^- \tau^+ \nu_{\tau}$ $R(D^0): B^+ \to D^0 \tau^+ \nu_{\tau}$ $R(D_{s}^{(*)}): B_{s}^{0} \to D_{s}^{(*)}\tau^{+}\nu_{\tau}$ $R(\Lambda_{\rm b}): \Lambda_{\rm b} \to \Lambda_{\rm c}^{(*)} \tau^+ \nu_{\tau}$

sensitivity to short-distance amplitudes

 $\mathcal{B}(D^0 \to \pi^+ \pi^- \mu^+ \mu^-) = (9.64 \pm 0.48_{\text{stat}} \pm 0.51_{\text{syst}} \pm 0.97_{\text{norm}}) \times 10^{-7}$ $\mathcal{B}(D^0 \to K^+ K^- \mu^+ \mu^-) = (1.54 \pm 0.27_{\text{stat}} \pm 0.09_{\text{syst}} \pm 0.16_{\text{norm}}) \times 10^{-7}$ 41

• $c \rightarrow u \mu^+ \mu^-$ FCNC transitions ($\mathcal{O}(10^{-9})$ in SM), potentially sensitive to NP • However, "long-distance" contributions, are expected to be large, reducing

- searches for NP

- signs of tension are emerging

Conclusions

• Precise measurements of flavour observables provide a powerful way to probe for NP effects beyond the SM, complementing direct

• Flavour-physics measurements at the LHC, in particular by LHCb, are dramatically adding to the already impressive knowledge accumulated by the B-factories and Tevatron

• Many world record results. For some topics we have moved from exploration to precision measurements

Most of these results show good compatibility with the SM, but some

• Need more data to test these hints. These data are arriving in Run 2!

A few extra slides

Crosschecks on bremsstrahlung recovery

• Relative population of bremsstrahlung categories compared between data and simulation using $B^0 \rightarrow K^{*0}J/\psi(ee)$ and $B^0 \rightarrow K^{*0}\gamma(ee)$ events

LHC Schedule & LHCb We are here ! 2018 2020 2023 Run3 LS2 Run2 14 TeV 13->14 TeV • LHCb is currently building its upgrade to be installed in LS2 • Aim: to collect 50 fb⁻¹ at $\mathscr{L} = 2 \times 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$

• Requirements: - 40 MHz readout - $\mathcal{L} = 2 \times 10^{33} \text{cm}^{-2} \text{sec}^{-1} (x 5)$

• Implications: - New HLT farm and network

LHCb Upgrade

- Event selection performed by HLT software only \rightarrow 5.5 visible interactions/crossing
 - \rightarrow Higher track multiplicity (from ~ <70> to <180>)

- New detector front-end electronics because of new readout requirement - New trackers with finer granularity to reduce occupancy

- What is not changed needs to be consolidated to sustain higher Luminosity
