Challenges in supersymmetric cosmology

I. Antoniadis

Albert Einstein Center, University of Bern LPTHE, Sorbonne Université, CNRS Paris Workshop on Connecting Insights in Fundamental Physics: Standard Model and Beyond 1-10 September 2019, Corfu, Greece

19th Hellanic School and Warkshops on Elementary Particle Physics and Gravity

Problem of scales

- describe high energy (SUSY?) extension of the Standard Model unification of all fundamental interactions
- incorporate Dark Energy

simplest case: infinitesimal (tuneable) +ve cosmological constant [4]

 describe possible accelerated expanding phase of our universe models of inflation (approximate de Sitter) [5]

 \Rightarrow 3 very different scales besides M_{Planck} : [6]

A well motivated proposal

addressing several open problems of the Standard Model

- natural elementary scalars
- realise unification of the three Standard Model forces
- natural dark matter candidate (lightest supersymmetric particle)
- addressing the hierarchy problem
- prediction of light Higgs ($\lesssim 130$ GeV)
- soft UV behavior and important ingredient of string theory

But no experimental indication of any BSM physics at LHC

It is likely to be there at some (more) fundamental level

Relativistic dark energy 70-75% of the observable universe negative pressure: $p = -\rho \Rightarrow$ cosmological constant

$$R_{ab} - \frac{1}{2}Rg_{ab} + \Lambda g_{ab} = \frac{8\pi G}{c^4}T_{ab} \Rightarrow \rho_{\Lambda} = \frac{c^4\Lambda}{8\pi G} = -p_{\Lambda}$$

Two length scales:

• $[\Lambda] = L^{-2} \leftarrow \text{size of the observable Universe}$ $\Lambda_{obs} \simeq 0.74 \times 3H_0^2/c^2 \simeq 1.4 \times (10^{26} \text{ m})^{-2}$ Hubble parameter $\simeq 73 \text{ km s}^{-1} \text{ Mpc}^{-1}$

•
$$\left[\frac{\Lambda}{G} \times \frac{c^3}{\hbar}\right] = L^{-4} \leftarrow \text{dark energy length} \simeq 85 \mu \text{m}$$
 [2]

Inflation:

Theoretical paradigm consistent with cosmological observations

But phenomelogical models with not real underlying theory [2]

Inflaton potential:

slow-roll region with V', V'' small compared to dS curvature

Direct connection of inflation and supersymmetry breaking:

identify the inflaton with the partner of the goldstino

Goldstone fermion of spontaneous supersymmetry breaking

while accommodating observed vacuum energy

Inflation in supergravity: main problems

Inflaton: part of a chiral superfield X

 \bullet slow-roll conditions: the eta problem \Rightarrow fine-tuning of the potential

$$\eta = V''/V, \quad V_F = e^{K} (|DW|^2 - 3|W|^2), \quad DW = W' + K'W$$

K: Kähler potential, *W*: superpotential Planck units: $\kappa = 1$ canonically normalised field: $K = X\bar{X} \Rightarrow \eta = 1 + ...$

trans-Planckian initial conditions ⇒ break validity of EFT
 no-scale type models that avoid the η-problem

 $K = -3\ln(T + \overline{T}); W = W_0 \Rightarrow V_F = 0$

- stabilisation of the (pseudo) scalar companion of the inflaton chiral multiplets => complex scalars
- moduli stabilisation, de Sitter vacuum, ...

Inflation from supersymmetry breaking I.A.-Chatrabhuti-Isono-Knoops '16, '17, '19

Inflaton : goldstino superpartner in the presence of a gauged R-symmetry

• linear superpotential $W = f X \Rightarrow$ no η -problem

 $V_{F} = e^{K} (|DW|^{2} - 3|W|^{2})$ = $e^{K} (|1 + K_{X}X|^{2} - 3|X|^{2}) |f|^{2}$ $K = X\bar{X}$ = $e^{|X|^{2}} (1 - |X|^{2} + O(|X|^{4}) |f|^{2} = O(|X|^{4}) \Rightarrow \eta = 0 + \dots$ linear W garanteed by an R-symmetry

- gauge R-symmetry: (pseudo) scalar absorbed by the $U(1)_R$
- inflation around a maximum of scalar potential (hill-top) ⇒ small field no large field initial conditions
- vacuum energy at the minimum: tuning between V_F and V_D

Case 1: R-symmetry is restored during inflation (at the maximum)

• Case 2: R-symmetry is (spontaneously) broken everywhere and restored at infinity example: $S = \ln X$

Case 1: R-symmetry restored during inflation

maximum at the origin with small η by a correction to the Kähler potential

$$\mathcal{K}(X,\bar{X}) = \kappa^{-2}X\bar{X} + \kappa^{-4}A(X\bar{X})^{2} \qquad A > 0 \qquad [12]$$

$$\mathcal{W}(X) = \kappa^{-3}fX \qquad \Rightarrow$$

$$f(X) = 1 \qquad (+\beta \ln X \text{ to cancel anomalies but } \beta \text{ very small})$$

$$\mathcal{V} = \mathcal{V}_{F} + \mathcal{V}_{D}$$

$$\mathcal{V}_{F} = \kappa^{-4}f^{2}e^{X\bar{X}(1+AX\bar{X})} \left[-3X\bar{X} + \frac{(1+X\bar{X}(1+2AX\bar{X}))^{2}}{1+4AX\bar{X}} \right]$$

$$\mathcal{V}_{D} = \kappa^{-4}\frac{q^{2}}{2} \left[1 + X\bar{X}(1+2AX\bar{X}) \right]^{2} \qquad [14] \qquad [16]$$

Assume inflation happens around the maximum $|X| \equiv \rho \simeq 0 \Rightarrow$

Predictions

slow-roll parameters $(q \simeq 0)$

$$\eta = \frac{1}{\kappa^2} \left(\frac{V''}{V} \right) = -4A + \mathcal{O}(\rho^2) \quad [14]$$
$$\epsilon = \frac{1}{2\kappa^2} \left(\frac{V'}{V} \right)^2 = 16A^2\rho^2 + \mathcal{O}(\rho^4) \simeq \eta^2\rho^2$$

η naturally small since A is a correction

inflation starts with an initial condition for $\phi=\phi_*$ near the maximum and ends when $|\eta|=1$

$$\Rightarrow \text{ number of e-folds } N = \int_{end}^{start} \frac{V}{V'} = \kappa \int \frac{1}{\sqrt{2\epsilon}} \simeq \frac{1}{|\eta_*|} \ln \left(\frac{\rho_{\text{end}}}{\rho_*}\right) \quad \text{[19]}$$

Planck '15 data : $\eta \simeq -0.02 \Rightarrow N \gtrsim 50$ naturally

Predictions

amplitude of density perturbations $A_s = \frac{\kappa^4 V_*}{24\pi^2 c} = \frac{\kappa^2 H_*^2}{8\pi^2 c}$ spectral index $n_s = 1 + 2\eta_* - 6\epsilon_* \simeq 1 + 2\eta_*$ tensor – to – scalar ratio $r = 16\epsilon_*$ Planck '15 data : $\eta \simeq -0.02$, $A_s \simeq 2.2 \times 10^{-9}$, $N \gtrsim 50$ \Rightarrow $r \lesssim 10^{-4}$. $H_* \lesssim 10^{12}$ GeV assuming $\rho_{\rm end} \lesssim 1/2$ Question: can a 'nearby' minimum exist with a tiny +ve vacuum energy? Answer: Yes in a 'weaker' sense: perturbative expansion [10]

valid for the Kähler potential but not for the slow-roll parameters need D-term contribution and next (cubic) correction in ${\cal K}$

Microscopic Model (see Chatrabhuti's talk)

Fayet-Iliopoulos model based on a U(1) R-symmetry in supergravity two chiral multiplets Φ_{\pm} of charges q_{\pm} and mass m and FI parameter ξ

 $W = m \Phi_+ \Phi_-$

- R-symmetry $\Rightarrow q_+ + q_- \neq 0$
- Higgs phase: $\langle \Phi_{-} \rangle = \nu \neq 0$

Limit of small SUSY breaking compared to the U(1) mass: $m^2 << q_-^2 v^2$

integrate out gauge superfield \rightarrow EFT for the goldstino superfield Φ_+

$$W = mv\Phi_+$$
; $K = \bar{\Phi}_+\Phi_+ + A(\bar{\Phi}_+\Phi_+)^2 + B(\bar{\Phi}_+\Phi_+)^3 + \cdots$

parameter space allows realistic inflation

and a nearby minimum with tuneable energy

Fayet-Iliopoulos (FI) D-terms in supergravity

D-term contribution: positive contribution to $\eta \Rightarrow$ should stay small $_{\rm [10]}$ its role: not important for inflation

- U(1) absorbs the pseudoscalar partner of inflaton
- allows tuning the EW vacuum energy

Question: is it possible to have inflation by SUSY breaking via D-term? the inflaton should belong to a massive vector multiplet as before

FI-term in supergravity very restrictive:

it gives a large positive mass to the inflaton

A new FI term was written recently Cribiori-Farakos-Tournoy-Van Proeyen '18 gauge invariant at the Lagrangian level but non-local

becomes local and very simple in the unitary gauge

A new FI term

Global supersymmetry:

$$\mathcal{L}_{\mathrm{FI}}^{new} = \xi_1 \int d^4\theta \frac{\mathcal{W}^2 \overline{\mathcal{W}}^2}{\mathcal{D}^2 \mathcal{W}^2 \overline{\mathcal{D}}^2 \overline{\mathcal{W}}^2} \mathcal{D} \overset{\checkmark}{\mathcal{W}} = -\xi_1 \mathrm{D} + \mathrm{fermions}$$

It makes sense only when $<\mathrm{D}>\neq$ 0 \Rightarrow SUSY broken by a D-term

Supergravity generalisation: straightforward unitarity gauge: goldstino = U(1) gaugino = 0 \Rightarrow standard sugra $-\xi_1 D$

Pure sugra + one vector multiplet \Rightarrow

$$\mathcal{L} = R + \bar{\psi}_{\mu}\sigma^{\mu\nu\rho}D_{\rho}\psi_{\nu} + m_{3/2}\bar{\psi}_{\mu}\sigma^{\mu\nu}\psi_{\nu} - \frac{1}{4}F_{\mu\nu}^{2} - \left(-3m_{3/2}^{2} + \frac{1}{2}\xi_{1}^{2}\right)$$

- $\xi_1 = 0 \Rightarrow AdS$ supergravity
- $\xi_1 \neq 0$ uplifts the vacuum energy and breaks SUSY e.g. $\xi_1 = \sqrt{6}m_{3/2} \Rightarrow$ massive gravitino in flat space

Net result: $\xi_1 \rightarrow \xi_1 e^{K/3}$

The new and standard FI terms can co-exist in a particular Kähler basis I.A.-Chatrabhuti-Isono-Knoops '18

 $K = X\bar{X} + b\ln X\bar{X} + A(X\bar{X})^2 \quad ; \quad W = f$

previous model: b = 1 in a different basis \Rightarrow (A = 0) [10]

$$\mathcal{V}_D = \frac{q^2}{2} \left(\rho^2 + b + \xi \, \rho^{\frac{4b}{3}} e^{\frac{1}{3}\rho^2} \right)^2 \quad \xi = \xi_1/q \quad \text{new FI term}$$

b : standard FI constant

<u>Case f = 0</u> (pure D-term potential) \Rightarrow model of inflation on D-term

maximum at $ho = 0 \Rightarrow b = 3/2$ and $\xi \leq -1$

Model of inflation on D-term

$$\mathcal{V}_{D} = rac{q^{2}}{2} \left[rac{3}{2} +
ho^{2} \left(1 + \xi e^{rac{1}{3}
ho^{2}}
ight)
ight]^{2}$$

- ξ = -1: effective charge of X vanishes
 (1 + ξ) plays the role of the correction A to Kähler potential
- \bullet supersymmetric minimum at D=0

Model of inflation on D-terms

Case $f \neq 0$:

- maximum is shifted at $\rho = -\frac{3f^2}{4(1+\xi)q^2}$
- minimum is lifted up and SUSY is broken by both D and F of $\mathcal{O}(f)$

slow-roll parameters

$$\eta = \frac{4(1+\xi)}{3} + \mathcal{O}(\rho^2)$$

$$\epsilon = \frac{16}{9}(1+\xi)^2 \rho^2 + \mathcal{O}(\rho^4) \simeq \eta^2 \rho^2$$

$$N \sim \frac{1}{|\eta_*|} \ln\left(\frac{\rho_{\text{end}}}{\rho_*}\right)$$

 \Rightarrow same main results as before (F-term dominated inflation) !! [11] However allowing higher order correction to the Kähler potential one can obtain *r* as large as 0.015 (near the experimental bound)

Conclusions

General class of models with inflation from SUSY breaking:

identify inflaton with goldstino superpartner

• (gauged) R-symmetry restored (case 1)

small field, avoids the η -problem, no (pseudo) scalar companion a nearby minimum can have tuneable positive vacuum energy

• D-term inflation is also possible using a new FI term

it allows for a positive uplifting of the scalar potential

it can lead to large r of primordial gravitational waves

Open question: string theory realisation

gauged R-symmetry, ordinary vs new FI-terms, explicit models
